Cryptography Practice

Part 1: Diffie-Hellman

Let's take turns playing all three parts in a Diffie-Hellman key exchange.

1a. You are Alice. You are trying to send a secret message to Bob (your partner), but Eve (the other group) is in the way and will read any paper planes you pass to Bob. You did not have the foresight to give Bob a one-time pad in advance, so you're going to have to create one on the fly using the Diffie-Hellman key exchange.

Select a and g using the table of primes. We'll use $m = 10,000$.

$$a_1 =$$

$$g_1 =$$

Compute $g^a \bmod m$.

$$g_1^{a_1} =$$

Transmit information to Bob. Write g_1 and $g_1^{a_1} \bmod m$ on a piece of paper, fold it up into a paper plane, and transmit it to Bob (...but remember, you can't stop the eavesdroppers from reading it!).

1b. You are Eve. Oh no, the other Alice-Bob pair is trying to transmit information to each other! Better intercept it! What does it say?

Nothing terribly useful yet, I expect.

1c. You are Bob. You (who were named Alice in 1a, but are now named Bob) have received a paper plane from Alice (who was named Bob in 1a, but is now named Alice). Let's try to finish up the key exchange with Alice, shall we?

Select b using the table of primes.

$$b_2 =$$

Compute $g^b \bmod m$.

$$g_2^{b_2} =$$

Transmit information to Alice. Write $g_2^{b_2} \bmod m$ on a piece of paper, fold it up into a paper plane, and transmit it to Alice (...but remember, you can't stop the eavesdroppers from reading it!).

Compute the secret for this key exchange. Remember, you need to find $g^{ab} \bmod m$.

$$(g_2^{b_2})^{a_2} =$$

1d. You are Eve, again. Oh no, the other Alice-Bob pair is trying to transmit information to each other! Better intercept it! What does it say?

Can you use the information you've gotten so far to compute their shared secret? Why or why not?

1e. You are Alice, again. Okay, so Bob finally got back to you with a value of b . (What, you mean you were named Bob before? Now you're named Alice again, just like in part 1a.)

Compute the secret for this key exchange. Remember, you need to find $g^{ab} \bmod m$.

$$(g_1^{b_1})^{a_1} =$$

Use the secret to send Bob a message! Pick your favorite number, add that number to the secret $(g_i^{b1})^{a1}$, and send the result to Bob on a paper airplane! Can you have Bob decrypt the result and tell it to you to confirm that everything happened all right? As Bob, can you decrypt your partner's message and confirm with them that you got their favorite number?

1f. You are Eve, a third time. You intercept the paper plane that contains someone's favorite number added to a shared secret – $n + g^{ab}$. You've intercepted g^a and g^b . Can you use this information to figure out n ? Why or why not?

How much computation would you have to perform in order to figure out the value of n – how many values of a , for example, would you have to calculate against in order to find an a that is clearly the a that was used to make the g^a you intercepted?
